

# A Case Study of Fine-Grained Software Compartmentalization using cURL

Stephen Carrasquillo | Junyong Zhao | Henry Zhu | Nik Sultana | Boon Tau Loo University of Pennsylvania

## Background

Compartmentalization breaks up functions into separate processes

LibCompart is a library currently being developed to make compartmentalization easier.

Compartmentalization is useful for information security since it limits access to sensitive information.

cURL is an **open source** file transfer utility.

It is widely distributed in many Linux distributions.

### Motivation

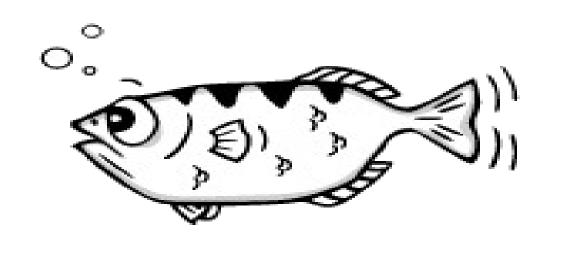

- Create a functioning version of cURL with compartmentalization using LibCompart.
- Examine the impact of compartmentalization on cURL's execution.

## Methodology

#### **Identify the critical functions**

Use **GDB** to step through cURL.

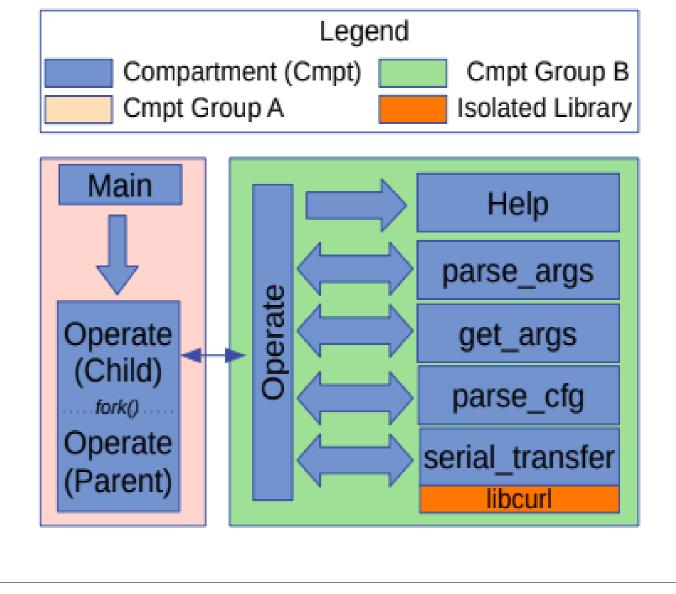

Key Functions are identified where the curl **interface** utilizes **instances** of curl-lib.

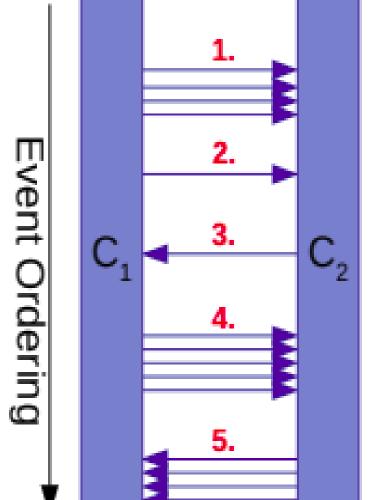

#### **Isolate functions**

Use **LibCompart** to assign functions to compartment calls.

Replace functions in source code with **compartment calls.** 

#### **Serialize Data Structures**

- Send individual Sub data structures (PUSH)
- Request Action with a parent data structure.
  Respond with result of
- action and the updated parent structure
- Request updated substructures (PULL)
   Update local children and parent.

Use the **serializer** tool to create stubs for marshalling and unmarshalling primitive data structures.

Create **synchronization** protocol for complex relationships.

#### **Test and Validate Results**

Create 2 test cases:

- Download of a simple web page (www.google.com) using cURL's HTTP module.
- Download of a 65MB video file from a local network server using cURL's FTP module.
- •Both Tests were performed 10X using a bash script to record the start and end time.

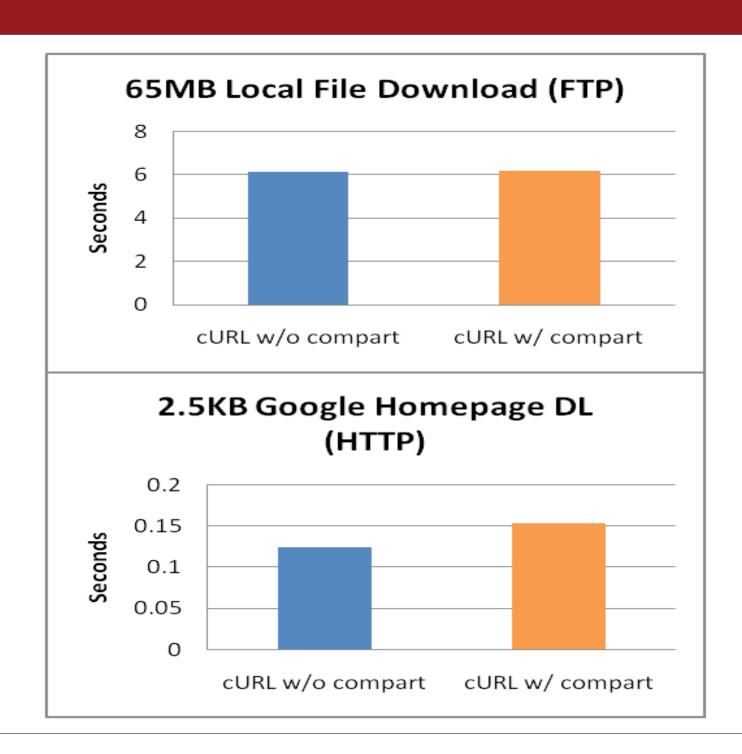

## Results / Findings

#### Performance:

- Compartments added on average 6ms to large data transfers and 30ms to smaller file downloads
- More testing and validation is required to understand the full impact of compartmentalization.

#### File Accuracy:

- Some changes were reported on the google web page download; However, these changes were expected as they are unique hashes for each page visit.
- The 65MB file reported no difference in cURL's the compartmentalized version.

## Final Thoughts

- Compartmentalization was successfully achieved with LibCompart in cURL's source code.
- While successful there are still challenges that need to be overcome.
- More compartmentalization efforts will be required to fully tackle these challenges.
